Abstract

The Cys2His2 zinc finger (ZF) is the most frequently found sequence-specific DNA-binding domain in eukaryotic proteins. The ZF's modular protein-DNA interface has also served as a platform for genome engineering applications. Despite decades of intense study, a predictive understanding of the DNA-binding specificities of either natural or engineered ZF domains remains elusive. To help fill this gap, we developed an integrated experimental-computational approach to enrich and recover distinct groups of ZFs that bind common targets. To showcase the power of our approach, we built several large ZF libraries and demonstrated their excellent diversity. As proof of principle, we used one of these ZF libraries to select and recover thousands of ZFs that bind several 3-nt targets of interest. We were then able to computationally cluster these recovered ZFs to reveal several distinct classes of proteins, all recovered from a single selection, to bind the same target. Finally, for each target studied, we confirmed that one or more representative ZFs yield the desired specificity. In sum, the described approach enables comprehensive large-scale selection and characterization of ZF specificities and should be a great aid in furthering our understanding of the ZF domain.

Cys2His2 Zn-finger:
Outline:

• **First**, we optimized a polymerase chain reaction (PCR)-based cassette mutagenesis method to build libraries of ZF proteins where up to six amino acid positions are varied, all 20 amino acids are possible and theoretical DNA library sizes of $3 \times 10^7$ and $1 \times 10^9$ are over-sampled by at least 5-fold.

• **Second**, we derived a simple analytical formula to calculate the expected diversity of a library and showed via high-throughput sequencing that the produced libraries offer levels of diversity that approach the theoretical maximum.

• **Third**, we used one of our ZF libraries with five varying amino acid positions in conjunction with the B1H system to select and deep sequence ZFs that bind several 3 bp targets of interest.

• **Fourth**, we developed an information-theoretic approach, based on the number of ways a protein sequence may be encoded that allowed us to uncover enriched ZFs (i.e. corresponding to ZFs binding the targets of interest) from large sequence pools that may contain considerable background.

• **Fifth**, because the sequencing depth of selected ZF pools resulted in thousands of enriched ZFs for each target, we clustered them to uncover distinct classes of similar amino acid profiles.

• **Finally**, for each target studied, we confirmed that one or more of the selected ZFs offer the desired specificity and further tested a subset of these to confirm that they can act as artificial TFs in yeast.
Step 1. Amplify fragments from parent template with appropriate oligonucleotide design.

Key components: 65-70°C TM
48-96 reactions
15-20 cycles

Step 2. Digest and ligate PCR fragments.

a. Digest with pre-designed, internal restriction site (green)
b. Ligate fragments to create full-length library template

Step 3. Amplify library cassette.

Key components: 48-96 reactions
30 cycles
External restriction sites (blue) used for cloning into final vector
Diversity of the designed libraries:

For a sequence with \( i \) variable amino acid positions, encoded by the NNS codons, the total possible number of encoding DNA sequence variants (\( N \)) could be computed as:

\[
N = (4*4*2)^i
\]

6 variable AA positions => \( N = 1.07 \times 10^9 \)

5 variable AA positions => \( N = 3.36 \times 10^7 \)

We can compute the expected number of distinct (or unique) sequences \( U \) observed in the ideal case with perfectly uniform distribution as a function of the total number sequenced \( n \) and the total number of possible variants \( N \) as:

\[
U = N \left( 1 - \left( 1 - \frac{1}{N} \right)^n \right)
\]
Library diversity determined by deep sequencing.

A bacterial one-hybrid system for determining the DNA-binding specificity of transcription factors.  
Processing zinc finger selection data:

The Shannon entropy, normalized by the number of possible ways to code the amino acid sequence using NNS codons, was used as a measure of the diversity with which that particular amino acid sequence was observed:

\[ E = -\frac{1}{\log_2 N} \cdot \sum_{i=1}^{N} p_i \log_2 p_i \]

where \( N \) is the total number of DNA variants to encode the current amino acid sequence and \( p_i \) the relative observation frequency of each such DNA sequence in the Illumina sequencing.

Amino acid sequences with either normalized entropy \( \geq 0.25 \) or that can only have a single possible encoding with NNS codons were retained for further analysis; the rest were removed, as the lack of diversity in their underlying coding sequences suggests that they may be artifacts.
Overview of the computational pipeline for zinc finger selection analysis.

Zinc finger library builds by PCR-driven cassette mutagenesis. **Important points at the core of the optimized method:**

- **First**, a separation of 20°C between the designed annealing temperature of the library oligo and the temperature performed in the PCR reaction minimizes any amplification advantage that one library member may have over another.

- **Second**, many reactions (48-96 per fragment) were carried out and pooled to dilute any bias that might occur in one reaction versus another.

- **Finally**, design of a restriction site at the 5’ end of the oligo allows for capture of full-length library fragments. These fragments can be captured by digestion and ligation with another fragment of DNA.
Applicability:

• The data can be leveraged to build predictive models of zinc finger binding specificity and to assemble zinc finger proteins with desired binding specificities. In the future, these techniques can be used to select new zinc finger domains to bind all possible targets.

• According to the authors, the high-throughput approach has the potential to greatly influence genome and protein engineering. Scaling this approach up may provide a deep understanding of the zinc finger and potentially other protein domains, allowing for the prediction of naturally occurring proteins and the design of novel ones.
